ABSTRACT

Objective: This work was connected to screen Helicobacter *pylori* among human in Erbil Governorate by using stool antigen test (SAT).

Methods: In a clean and sterile container, three hundred stool samples were collected from both sexes during the period from July-December 2017. Samples were collected from 150 males at the rural and an urban area in equal number, similarly 150 females same areas. The collected samples were tested in Microbiology Laboratory, Department of Pathological Analysis using One-Step *H. pylori* Antigen Test Kit.

Results: The obtained results shown that the prevalence of *H. pylori* in total samples were (11.3%). The rate of infection among females were (12.7%) compared to (10.0%) of male infection rate. According to the age wise of the patients (11-20, 51-60 and above 60 y) results showed that the *H. pylori* antigen rates were (16.3%, 11.9%, and 13.6%) respectively that mean the high rate of infection was varied. According to habitation, the high rate of *H. pylori* among males was 12.0% and 8.0% in rural and urban area consecutively. While the occurrence rate of *H. pylori* antigen among female was high 14.7% in rural area, compared to 10.7% in the female of the urban area. The proportion of *H. pylori* antigen rate in September, December and October were (16.0%, 14.0%, and 12.0%) respectively.

Conclusion: From this study, we concluded that the prevalence of *H. pylori* among human in Erbil Governorate was high, and the infection takes place in the early years of life. The significance of public health risks was discussed.

INTRODUCTION

Helicobacter pylori is associated with gastro-duodenal infections in human. *H. pylori* have been found strongly related to chronic gastritis, duodenal ulcer, gastric carcinoma, and mucosa-associated lymphoid malignancies. Gastric cancer is the most common infection-related cancer globally, which led to the categorization of *H. pylori* as a class one human carcinogen by the international agency for research on cancer (IARC), also several researchers confirmed that *H. pylori* is the most common infectious human pathogen [1-3].

Basically, *H. pylori* have a narrow host range and found in humans and some nonhuman primates. Occasionally, *H. pylori* have been isolated from domestic animals, but until now there is no available evidence for zoonotic transmission of *H. pylori*. Several investigations address the role of food in the transmission of *H. pylori*. Food is a reasonable source of infections with *H. pylori*, and there are several investigations which address the role of food in the transmission of *H. pylori*. Various works support the suggestion of H. *pylori* waterborne pollution, and there are abundant epidemiological works have indicated positive relations between untreated or fecal polluted drinking water and occurrence of *H. pylori* contamination. Also, several studies have reported the presence of *H. pylori* DNA in the environmental water sources [4-7].

H. pylori are actually a frequent infection all over the world. It is one of the world's most common public health issues**.** The rate of *H. pylori* infection is still high in most of the countries. There were approximately 4.4 billion individuals among both developed, and developing countries are infected with *H. pylori* worldwide in 2015 making it one of the most debatable bacteria in the world. Over 80% of individuals infected with the bacterium are asymptomatic. In diverse developing countries, more than 80% of the people are *H. pylori* positive, while in developed countries in general remains below 40% and is significantly lower in children and adolescents than in adults and elderly people [8-9].

In daily medical career, the use of a single test is usually sufficient, and most tests are adequately perfect to be used for this purpose, also the use of serology is most suitable for large epidemiological studies. The application of Stool Antigen Test (SAT) for general detection of *H. pylori* offers the opportunity to evaluate *H. pylori* condition without the need for endoscopy or venal puncture [10-11].

The objectives of this investigation were to monitor the prevalence of *H. pylori* among human males and females in both Rural and Urban areas.

MATERIALS AND METHODS

Study design and sampling

Three hundred (300) human stool samples were collected during the period from July 2017 to December 2017. Samples were collected from 150 male (comprised75 samples from rural area and75 samples from an urban area), and 150 female (included 75 samples from the rural area and 75 samples from an urban area). All males and females ranged in age from one year to more than>61 y. Stool specimens were collected in sterile containers [12]. The collected samples were forwarded to the Microbiology Laboratory, Department of Pathological Analysis/College of Science/Knowledge University.

Personal information

Information about persons was recorded, including gender, age, and place of habitation. This work has been connected according to the Order No: PL/KU11/2017. From the Department of Pathological Analysis, College of Science/Knowledge University. Dated on 15/May/2017, to Dr. Dhary Alewy Almashhadany to screen the rate of pathogenesis rate of *H. pylori* in rural and an urban area in Erbil.

Detection of *H. pylori* antigen in stool

In the laboratory, the detection of *H. pylori* antigen in stool samples was done by using the One-Step *H. pylori* Antigen Test Card (RAPID

TEST/www. plasmatec. uk. com) fig. 1. The test was carried out according to [13]. The subsequent steps were followed:

Fig. 1: Photo of the kit (F= front, B = back)

Samples preparation

All materials and specimens were put in room temperature before used. The sample bottles unscrewed. With the help of an attached applicator stick on the cap a small piece of stool (5-6 mm in diameter, approximately 100 mg-200 mg/0.1-0.2 g) transferred into the sample bottle containing specimen preparation buffer. The sticks in the bottles were replaced again to the specific bottles according to the giving numbers and tighten securely. Stool sample with the buffer mixed thoroughly by shaking the bottle for a few seconds.

Testing of the samples

Test cards were removed from the sealed foil pouch and the sample bottles well shake before the test performed. The bottles were held properly in a vertical position over the sample, about 3 drops (120-150µl) of diluted stool sample to the sample hole. The result was read within 10-15 min. A strong positive sample may show the result earlier.

Interpretation of result

Positive result

A distinct pink coloured band appears on test line regions, in addition to a pink line in the control line region.

Negative result

No line appears in the test line region. A distinct pink line shows in the control line region.

Statistical analysis

Data were analyzed using the Chi-Square test and SPSS software version 15.

RESULTS

Prevalence of *H. pylori* among human according to gender

Table 1 shown that the total prevalence of *H. pylori* among human was 34 (11.3%), also the result showed that the females is more exposed 19 (12.7%) to the infection with *H. pylori*, compared with male rate 15 (10.0%).

Table 1: Prevalence of *H. pylori* according to gender

Gender	No of samples examined	Positive		Negative		Chi-square	P value
		No	%	No	%		
Male	150	15	10.0	135	90.0	0.531	0.466 NS
Female	150	19	12.7	131	87.3		
Total	300	34	11.3	266	88.7		

Prevalence of *H. pylori* according to age

The obtained result in table 2 showed that the occurrence rate of *H. pylori* was high (16.3%) among the age group between 11-20 y, followed by the group which aged more than sixty-one>61 y (13.6%), and the lower occurrence rate was observed in the group aged between 51-60 y (11.9%).

Table 2: Prevalence of *H. pylori* antigens according to age

Age group (Years)	No of samples examined	Positive		Negative		Chi-square	P value
		No	%	No	%		
1–10	42	3	7.1	39	92.9	2.307	0.889 NS
11–20	43	7	16.3	36	83.7		
21–30	45	5	11.1	40	88.9		
31–40	43	4	9.3	39	90.7		
41–50	41	4	9.8	37	90.2		
51–60	42	5	11.9	37	88.1		
>61	44	6	13.6	38	86.4		
Total	300	34	11.3	266	88.7		

Prevalence of *H. pylori* in males according to habitation site

According to table 3 the habitation site of the male participants shown that the high proportion of *H. pylori* antigen was (12.0%) in a rural area, whereas (8.0%) among an urban area.

Prevalence of *H. pylori* in females according to habitation site

In table 4 results indicate that the incidence rate of *H. pylori* was high (14.7%) in female participants among rural area, whereas (10.7%) in female participants among an urban area.

Table 3: Prevalence of *H. pylori* in male's samples

Habitation site	No of samples examined	Positive		Negative		Chi square	P value
		No.	%	No.	%		
Rural Area	75	9	12.0	66	88.0	0.667	0.414
Urban Area	75	6	8.0	69	92		NS
Total	150	15	10.0	135	90.0		

Table 4: Prevalence of *H. pylori* in female's samples

Habitation site	No of samples examined	Positive		Negative		Chi square	P value
		No.	%	No.	%		
Rural Area	75	11	14.7	64	85.3	0.542	0.461
Urban Area	75	8	10.7	67	89.3		NS
Total	150	19	12.7	131	87.3		

The relationship between months and prevalence of *H. pylori* during the period of study

Table 5 points up the relationship between months and prevalence of *H. pylori* among human during the period of study. From this table we indicated that the highest rate of occurrence of *H. pylori* was founded in September (16.0%), then in December (14.0%), while the lowest rate was found in July and August (8.0%) for both of them.

Table 5: Relationship between Months and prevalence of *H. pylori*

Month	No of samples examined	*H. pylori* antigen		Chi-square	P Value
		No	%		
July	50	4	8.0	2.654	0.753
August	50	4	8.0		NS
September	50	8	16.0		
October	50	6	12.0		
November	50	5	10.0		
December	50	7	14.0		
Total	300	34	11.3		

DISCUSSION

H. pylori is a very sophisticated bacteria which is prevalent all over the world. The accurate timing of acquirement of *H. pylori* is unknown. The epidemiological evidence illustrated that infection takes place mostly in children under the age of 5 y, that is mean most of the people acquire *H. pylori* infection during their early childhood [14].

Several studies reported that 90% of duodenal ulcers and 70% of gastric ulcers are related to *H. pylori* infections. It is the major cause of peptic ulcer disease and gastric cancer, further, it possesses the enzyme urease, which hydrolyzes urea in the stomach into carbon dioxide and ammonia. This enables the survival of the bacterium in the acidic environment of the stomach, and causes bad breath (halitosis) and belching for the person and it equalizes the acidifying effects of hydrochloric acid [2-3].

Noninvasive tests are of major significance for assessment of the patient's status concerning infection by H. *pylori*. Stool antigen test (SAT) is an affordable, simple, low cost, sensitive, easiest methods to apply, also is considered the rapid diagnostic technique which is reliable, and the most globally used for identifying *H. pylori.*

In the present study, the prevalence of *H. pylori* among human was 11.3%. This value is an approach to those reported in Makkah city, Saudi Arabia (12.3%) [15], slightly approach with Namakin and Nejad [16] in Iran, who found the prevalence of *H. pylori* colonization in 282 students was 13.1%. However, our finding was lower than those reported in some other countries by using SAT, the prevalence of *H. pylori* infection in Turkey was 63% [17], 66.0% in China [18], and 37.8% in Iran [19].

In other hand, Sykora [20] found the prevalence of *H. pylori* infection in asymptomatic children in the Czech Republic at a rate of 7%. Recent studies conducted by several researchers reported different ranges of *H. pylori* infection; Daugule *et al.*, [221] in Latvia confirmed that (17.7%) of the total 220 patient samples was positive to SAT; in Korea Moon *et al.*, [22] reported that from 318 seropositive subjects, 256 (80.5%) showed positive stool test; El-shabrawi *et al.*, [23] in Egypt, reported that the *H. pylori* SAT test was positive in 34 (89.5%) out of the 38 patients.

Also from table 1, we noticed that the highest rate of prevalence of *H. pylori* antigens was found in female (12.7%), while the lowest rate of prevalence was found in male (10.0%), that means no significant differences between the prevalence rate among sexes at tha value of (p>0.05). This data was consistent with Yucel *et al.*, [17] in Turkey, who stated that the exposed to infection with *H. pylori* in females (76.2%) compared with (23.8%) in male by using monoclonal *H. pylori* SAT test. Elshiekh *et al.*, [24] in Egypt, reported that the rate of infection in females and males were 52% and 48% consecutively. While in a different way the results in this work inconsistent with Faisal *et al.*, [25] in Pakistan, who declared that the prevalence of *H. pylori* infection in female was 28.6%, while in male was 71.4%.

In table 2 the prevalence of *H. pylori* antigens among human in the age shown that there are no significant differences in the *H. pylori* antigen test between age groups according to positive and negative results in the value of (p>0.05).

The current result was incompatible with the result stated by Mayass [13], who confirmed that the prevalence of *H. pylori* antigen among human stool samples was (18.4%)**,** they found that the high prevalence rate of *H. pylori* antigen in the stool of children was between the age group of 11-15 y (28.6%), followed by the children with age group between one month–5 y (9.7%), whereas the prevalence of *H. pylori* antigen from adult stool was high in the ages between 46-55 y (25.0%), followed by group with age between 26-35 y (23.4%), then from 56-65 y were (23.1%), after that from 36-45 y (18.2%), finally the age of 16-25 y were (15.4%). Bader *et al.*, [26] in Egypt found that the prevalence of *H. pylori* antigen in the stool of children<5 y was 30%, followed by age group between 5-10 y was (40%), finally age group>10 y the rate was (20%). In Yemen (Taiz city)**,** Naji *et al.*, [27] reported that the stool antigen was positive in (49%) out of 100 samples tested, and the majority of cases were in the age group between 40-49 y, also they confirmed that the predominance of infection was for the female.

Recently AL-Sinani *et al.*, [28] in Oman, the general occurrence of *H. pylori* in Omani children increased from 7% in an age of less than five years to 33% in the age group between 5-10 y. Also, Awuku *et al.*, [29] in Ghana, stated that the overall prevalence of *H. pylori* infection among children was 14.2%, and the age group with the lowest *H. pylori* infection rate was 14–16 y with the prevalence of 11.9%, they also noticed that a female: male ratio of 1.3:1, with a higher ratio of females (16.8%) having *H. pylori* infection, compared to males (10.7%).

The high incidence of *H. pylori* infection in adult life can possibly be elucidated by the exposure of the community to *H. pylori* early in life because of risk factors, like poor sanitation, lack of proper hygiene and increased receptivity due to a genetic tendency. Overcrowding is a risk factor for acquisition of *H. pylori* infection in children; contaminated water and food also act as sources of infection. The epidemiological articles published at the start of this decade.

supported the indication that *H. pylori* are most common in impoverished areas with poor sanitation, overcrowding, low socioeconomic status, as well as the level of educational background, and rates of immigrant children from the adjacent cities are important risk factors for *H. pylori* infection among children. Transmission occurs during childhood through an oral–oral or a fecal-oral route [30-31].

According to the table 3, we observed that the high dominance of *H. pylori* antigen among males were (12.0%) and (8.0%) in rural and an urban area consecutively. That means *H. pylori* was prevalent in both of these areas. There is no significant difference in the *H. pylori* antigen test for male according to habitation for positive and negative samples (p>0.05).

Similarly, table 4 shown that the incidence rate of *H. pylori* antigen was high (14.7%) in female participants among rural area, whereas (10.7%) in female participants among an urban area. The obtained results indicated that there was no significant difference at the level of (p>0.05) in the *H. pylori antigen* test for females, according to habitation site for positive and negative examined samples.

The relationship between months and prevalence of *H. pylori* antigen during a study period were recorded. Results in table 5 clarify that the prevalence increased in September (16.0%), December (14.0%), October 12.0%, and November 10.0%. While in the month of July and August, the prevalence rate was (8.0%) for both. The statistical analysis of differences in the *H. pylori* antigen test for six months, according to our results shown that there were no significant differences in (p>0.05). The results are compatible somewhat with the work conducted by Mayass [13], who indicated that the prevalence increased in March and September (100%). After that in May and February, the incidence rate was (95.45%) and (95.00%) consecutively. Mayass [13] also reported that the rate of occurrence was declined whenever moved away from these months, in June (79.17%), July (75.00%), followed by October (73.91%), August (70.83%), lastly in April (56.52%). There are some limitations of our present work. First, the persons shown discomfort regarding specimen sampling. The sensitivity of this test decreases after using of the proton pump inhibitor therapy (PPI), bismuth and antibiotic.

CONCLUSION

H. pylori is one of a significant public health challenge for Iraqi Kurdistan. According to the results obtained from this work, we concluded that the occurrence of *H. pylori* antigen among humans in Erbil Governorate was so high. The significant occurrence of *H. pylori* infection may be due to overcrowding, socioeconomic status, level of educational background, family dietary, sanitary conditions, and rates of immigrant children from the adjacent towns or maybe because of other risk factors, like bad sanitation, lack of proper hygiene, and increased susceptibility as a result of a genetic tendency.
